

A METHOD FOR THE ABSORPTION OF A GAS IN A LIQUID AND AN
APPARATUS FOR THIS

This invention relates to a process for producing a solution of a gas in a liquid in which the gas is soluble, the solution having a predetermined concentration up to saturation, and to apparatus therefor.

Dissolution of a gas in a liquid is generally called absorption and may take place in several known and common ways. The absorption can be performed in a tower, a so-called absorption tower, in which the gas flows in counterflow relation to a circulating liquid. It can also be performed by means of a liquid jet pump, the absorption taking place in the minute droplets formed in the jet of liquid. Several other techniques can also be employed, mostly in counterflow, so that the largest possible contact surface between gas and liquid is provided for the absorption.

Common to the known methods to accomplish absorption and to the existing absorption apparatus is their requirement for more or less continuous manual monitoring. They also require a system of components which may be large or complicated. This is undesirable if the process is to form part of a complex process, having regard to its effectiveness, space requirements, safety aspects, operational requirements and economy. It is often necessary to be able to perform the absorption within a wide interval of flow rates and to be able to select the concentration of the solution that is produced. It may also be necessary that the gas be almost completely absorbed by the liquid so that there will be no need to take care of the sometimes poisonous or environmentally dangerous gas. Moreover, small dimensions may be called for to save space or in view of the materials used.

The object of the invention is to provide a process and suitable apparatus for performing a controlled gas-liquid absorption without extensive monitoring of the process and at the same time essentially avoiding the disadvantages mentioned initially.

To that end, the process and the apparatus according to the invention have the features set forth in the accompanying claims.

In accordance with the invention, the gas and the liquid are brought together under controlled supply in a proportion corresponding to the predetermined concentration of the solution. The gas and the liquid are caused to form a stream passing through a common conduit. The gas and the liquid are caused to intermix under the action of gravity and the intermixing is repeated before there is time for the gas and the liquid to separate, so that the gas is substantially absorbed in the liquid, forming a gas-liquid solution of the predetermined concentration.

Preferably, the process is carried out such the stream is brought into turbulence for intensifying the intermixing of the gas and the liquid. Suitably, the mixing is carried out at a pressure above the atmospheric pressure.

The process is generally useful for any combination of gas and liquid, especially combinations in respect of which performing the absorption is complicated, such as when the solubility is low. However, the process is particularly suited for absorption of chlorine gas in water if what is required is a chlorine gas solution whose concentration is to be chosen within a wide range and which has a wide range of flow rates and where small dimensions of the apparatus is more or less a must in view of problems related to materials and environment concerns:

The apparatus according to the invention comprises a conduit including a continuous tubular coil formed with a plurality of upwardly and downwardly directed sections. Suitably, elements generating turbulence are disposed within the tubular coil, and preferably a pressure-sustaining valve is provided to maintain a predetermined overpressure in the conduit. At least the tubular coil is preferably installed in a protective pressure-proof enclosure. The tubular coil may suitably be provided with packing bodies and/or folds for intensifying the intermixing of the gas and the liquid. Suitably, the tubular coil is shaped as a horizontal helix

of a length that may vary in accordance with the absorption process to be performed.

The invention will now be described in greater detail with reference to the accompanying drawing, which illustrates the principle of a preferred apparatus for performing the absorption.

Absorption of a gas in a liquid takes place through a controlled supply of gas, such as chlorine gas, to a conduit A and of liquid, such as water, to a conduit B in a conduit system. During the course of the absorption, a constant proportion between the gas flow rate and the liquid flow rate can be maintained in the system by means of a restrictor device 2 for the gas and a restrictor device 4 for the liquid. Pressures can be measured in the system by means of a number of pressure indicators (P1), and the flow rates can be measured by means of a number of flow indicators (F1) in the conduits. The streams of gas and liquid meet, whereupon dispersive admixing of the gas with the liquid takes place and the liquid is caused to proceed in the system under a certain overpressure through a continuous tubular coil 5 formed with a plurality of upwardly and downwardly extending tubular parts, which form a horizontal helix or a similarly shaped structure. As the gas and the liquid proceed through the turns of the coil 5, they are repeatedly mixed so that a favourable contact area between the gas and the liquid is constantly maintained. To intensify the intermixing, the tubular coil 5 suitably is provided with elements, not shown in the drawing, such as folds, for causing turbulence in the flowing stream and thereby making the absorption more efficient. The number of turns of the tubular coil 5 may also be varied to optimize the absorption. Moreover, the tubular coil 5 may be provided with packing bodies, which favour the absorption so that a shorter tubular coil 5 can be used. An overpressure (P4) is maintained in the apparatus by means of a pressure-sustaining valve 6 to speed up the process. The gas-liquid mixture exits the conduit system through a connector C.

For safety reasons, it may be important to prevent reverse flow in the gas conduit A and in the liquid conduit B. To that end, ordinary check valves are not

adequate, and it is preferred to monitor the pressures in these conduits. The condition to satisfy is that the pressures $P1 > P2 > P3$, and if that condition is not satisfied, the valves 1 and 3 are automatically closed to prevent reverse flow. It is also possible to monitor and control the flow rates q_1 and q_2 to prevent reverse flow.

The invention provides a number of important advantages in comparison with prior art processes. These advantages may be summarised as follows.

- The absorption is effective within a wide range of flow rates because the intermixing of gas and liquid takes place only with the aid of gravity and is repeated for each turn of the coil, as contrasted with, for example, a static mixer or similar apparatus, where adequate turbulence is obtained only within a narrow range of flow rates.
- The absorption can be made more efficient by means of folds or packing bodies in the tubular coil, which permit increased turbulence and improved contact between the gas and the liquid.
- The absorption can also be speeded up by placing the system under a suitable predetermined overpressure. The expensive materials which are often required in corrosive environments, such as chlorine, call for a compact material-saving unit.
- There is no need for separate disposal of gas, because the liquid flow rate is adjusted for dissolution of the gas.
- When chlorine is processed, the system contains less chlorine than is otherwise possible, and thus less chlorinated water has to be processed. As a result, there is less danger of leakage and, accordingly, an improved environment and an improved personal safety.

- There is no need for a circulating quantity of liquid, that is, there is only a "single" flow path.
- A compact construction is possible, which permits the tubular coil and, possibly, the entire system to be housed in a pressure-proof enclosure if particularly stringent demands with respect to environment and safety have to be met.
- The apparatus is believed to be less costly than existing systems, because its components and/or parts can have small dimensions.

Claims

1. A process for producing a solution of a gas in a liquid in which the gas is soluble, the solution having a predetermined concentration up to saturation, **characterised** in that the gas and the liquid are brought together under controlled supply in a proportion corresponding to the predetermined concentration of the solution, in that the gas and the liquid are caused to form a stream passing through a common conduit, in that the gas and the liquid in the stream are caused to intermix under the action of gravity, and in that the intermixing is repeated before the gas and the liquid have separated, so that the gas is substantially absorbed in the liquid, forming a gas-liquid solution of the predetermined concentration.
2. A process according to claim 1, **characterised** in that the stream is brought into turbulence for intensifying the intermixing of the gas and the liquid.
3. A process according to claims 1 and 2, **characterised** in that the intermixing is carried out at a pressure above the atmospheric pressure.
4. A process according to any one of claims 1 to 3, **characterised** in that the gas is chlorine and the liquid is water.
5. Apparatus for performing the process according to claim 1, **characterised** by a continuous tubular coil formed with a plurality of upwardly and downwardly directed tubular parts.
6. Apparatus according to claim 5, **characterised** in that elements producing turbulence are provided in the tubular coil.
7. Apparatus according to claims 5 and 6, **characterised by** a pressure sustaining valve which maintains a predetermined overpressure in the conduit.

8. Apparatus according to any one of claims 5 to 7, **characterised** in that at least the tubular coil is installed in a protective pressure-proof enclosure.
9. Apparatus according to any one of claims 6 to 8, **characterised** in that the tubular coil provided with packing bodies and/or folds.
10. Apparatus according to any one of claims 5 to 8, **characterised** in that the tubular coil is shaped as a horizontal helix.
